

Assignment 2

1) (a)

```
No1 = 10
```

```
print(no No1)
```

(b)

```
No1 = 10
```

```
print(no No1)
```

```
print(type(no No1))
```

(c)

2) It considers $a=10$ & $b=10$ as integers internally whereas it considers

```
a = [10]
```

```
b = [10] as
```

as list internally.

$a=10$ & $b=10$ has same memory address.

```
a = [10]
```

```
b = [10]
```

has different memory address.

3) `id()` function returns the unique identifying (memory address of an object). If two variables are storing 2 different values then the value returned by `id()` is the memory address. This memory address is same.

4) `getsizeof()` function returns the memory size ~~of~~ occupied by an object.

5) The output of the program is true.

both a & b reference the same object hence it's true.

6) No1 = 10

No2 = 20

print ("Addition is " + No1 + No2)

print ("Subtraction is " + No2 - No1)

print ("Multiplication is " + No1 * No2)

print ("Division is " + No2 / No1)

7) ~~raw~~ No1 = input()

7) No1 = int(input("enter a no"))

8) it will return the datatype as string as the input() function always returns a string.

10) The output will be
1020
30

9) name = "ayush"

age = 18

print ("Hi", name, "you will turn",
age + 1, "next year")
